[2] Landau Institute for Theoretical Physics, Moscow, Russia

ABSTRACT. All non-equivalent integrable evolution equations of the fifth order of the form $u_t = D_x \frac{\delta H}{\delta u}$ are found.

1. Introduction.

Consider integrable Hamiltonian evolution equations of the form

$$u_t = D_x \left(\frac{\delta H}{\delta u} \right). \tag{1.1}$$

Here $H(x, u, u_x, ...)$ is the Hamiltonian and D_x is the total x-derivative. By integrability we mean the existence of infinite hierarchy of commuting flows (or the same higher symmetries) for (1.1). The celebrated KdV equation with $H = -\frac{1}{2}\, u_x^2 + u^3$ provides the simplest example of such an equation.

In [1] integrable equations (1.1) of the third order have been investigated. Such equations have the form

$$u_t = D_x \left(\frac{\partial H}{\partial u} - D_x \frac{\partial H}{\partial u_x} \right), \tag{1.2}$$

where $H = H(x, u, u_x)$. It follows from the simplest necessary integrability condition [2, 3] that there exist two different kinds of integrable Hamiltonians:

$$H = a_1 u_x^2 + a_2 u_x + a_3 \qquad \text{and} \qquad H = k_1 u_x + k_2 + \sqrt{k_3 u_x^2 + k_4 u_x + k_5},$$

where a_i and k_i are some functions of u and x. Since the function H is defined up to the equivalence $H \to H + D_x f(x, u) + \lambda u$, we may put without loss of generality $a_2 = k_1 = 0$.

The following statement lists all integrable Hamiltonians up to canonical transformations (see Section 2).

Theorem 1. *Suppose that non-linear equation* (1.2) *has infinite hierarchy of higher symmetries*

$$u_{\tau_k} = F_k(x, u, u_x, \dots), \qquad k = 1, 2, \dots.$$

Then the Hamiltonian H is canonically equivalent to one of the following functions:

$$H = -\frac{u_x^2}{2\,Q(u)^3} + \frac{P(u)}{Q(u)}, \tag{1.3}$$

$$H = -\frac{u_x^2}{2\,u^3} + \frac{1}{3}P(x)u^3, \tag{1.4}$$

$$H = \sqrt{u_x + P(u)}. \tag{1.5}$$

Here P and Q are arbitrary polynomials of degrees not greater than 4, and 2, correspondingly.
□

In this paper we consider the fifth order integrable Hamiltonian evolution equations of the form

$$u_t = D_x\left(\frac{\delta H(x,u,u_x,u_{xx})}{\delta u}\right) = D_x\left(\frac{\partial H}{\partial u} - D_x\frac{\partial H}{\partial u_x} + D_x^2\frac{\partial H}{\partial u_{xx}}\right). \tag{1.6}$$

It turns out that there exist two types of integrable Hamiltonians:

$$H = a_1u_{xx}^2 + a_2u_{xx} + a_3 \qquad \text{and} \qquad H = k_1u_{xx} + k_2 + \sqrt[3]{u_{xx} + k_3},$$

where a_i and k_i are some functions of u, u_x and x.

Using the symmetry approach to integrability [2,3], we obtain a complete list of canonical forms for integrable Hamiltonians H. Our proof of the classification statement contains an algorithm which allows to bring any integrable Hamiltonian to one of the canonical forms by canonical transformations.

The list contains Hamiltonians for all fifth order commuting flows of equations from Theorem 1. For example, the Hamiltonian

$$H_1 = \frac{1}{2}u_{xx}^2 - 5\,uu_x^2 + \frac{5}{2}u^4$$

generates the fifth order equation from the KdV hierarchy. Besides these Hamiltonians, we found the following integrable Hamiltonians of second order:

$$H = \sqrt[3]{u_{xx} + (5\,u^2 + 9\,k)u_x + 2\,u\,(u^2+k)(u^2+9\,k)}, \tag{1.7}$$

$$H = \sqrt[3]{u_{xx}} + \frac{1}{3}\,c_0\,u^3 + \frac{1}{2}\,(c_1x + c_2)u^2 + (c_3x^2 + c_4x)u, \tag{1.8}$$

$$H = \frac{1}{2}\,{u_{xx}}^2 - \frac{5}{6}\,u_x^3 + \frac{5}{2}\,u^2u_x^2 + \frac{1}{6}\,u^6, \tag{1.9}$$

$$H = \frac{1}{2}\,\frac{{u_{xx}}^2}{u^{10}} - \frac{20}{3}\,\frac{{u_x}^4}{u^{12}} + \frac{5}{3}\,\frac{{u_x}^3}{u^{10}} + \frac{5}{2}\,\frac{{u_x}^2\,(ku+2)^2}{u^8} + \frac{20}{3}\,\frac{k^3}{u} + 10\,\frac{k^2}{u^2} + 8\,\frac{k}{u^3} + \frac{8}{3\,u^4}. \tag{1.10}$$

The constant k can be reduced to $k=0$ or to $k=1$ by a scaling. The constants c_i are also not essential (see Remark 4). Notice that the equation

$$u_\tau = D_x\frac{\delta}{\delta u}\left(\frac{1}{2}\,(c_1x+c_2)u^2+(c_3x^2+c_4x)u\right)$$

is the classical symmetry for the Hamiltonian equation with H given by (1.8).

It follows from [4, 5] that if the right hand side of integrable Hamiltonian equation

$$u_t = u_n + F(x,u,\,u_x,\,u_{xx},\dots,u_{n-1}), \qquad u_i=\frac{\partial^i u}{\partial x^i}. \tag{1.11}$$

is polynomial and homogeneous, then the hierarchy of this equation contains an equation of third or fifth order. This statement looks very credible also without any additional restrictions for the right hand side of the equation. The proof in the general case is absent and this statement has a status of the conjecture well-known for experts. No counterexamples to this conjecture are known.

Up to this conjecture, in this paper taken together with [1] we have described simplest equations for all hierarchies of the integrable Hamiltonian equations of the form (1.1). In other words, any integrable equation (1.1) is equivalent to a generalized symmetry of one of the equations presented in our papers.

2. Preliminaries.

2.1. **Canonical transformations.** It is easy to verify that the equation (1.6) is stable under transformations $H\to H+D_xf(x,u,u_x)+\lambda u$, where the function f and the constant λ are arbitrary.

Some transformations preserve the Hamiltonian form (1.6) changing the right hand side of equation. We call such transformations *canonical*.

Consider point transformations of the form

$$x=\varphi(y,v), \qquad u=\psi(y,v). \tag{2.1}$$

The invertibility of the transformation is equivalent to the inequality $\Delta=\varphi_y\psi_v-\varphi_v\psi_y\neq 0$. Transformation (2.1) is called *canonical* if $\Delta=\varphi_y\psi_v-\varphi_v\psi_y=1$. It is easy to verify that canonical transformations preserve the form of equation (1.6). The Hamiltonian of the resulting equation is given by

$$\tilde H(y,v,v_y)=H\left(\varphi(y,v),\psi(y,v),\frac{D_y(\psi)}{D_y(\varphi)}\right)D_y(\varphi). \tag{2.2}$$

Example. Linear transformations of the form

$$x=f(y), \qquad u=\frac{v}{f'}+g(y), \qquad \tilde H=Hf'.$$

are canonical for arbitrary functions f and g.

Remark 1. If we consider only Hamiltonians that do not depend on x explicitly, we still have non-trivial canonical transformations

$$x = f(v) + y, \quad u = v, \qquad \tilde{H} = (f' v_y + 1)\, H.$$

$$x = v, \quad u = f(v) + y, \qquad \tilde{H} = H\, v_y. \qquad \square$$

Besides (2.1) we use the following canonical transformations of a more general form:

1. Dilatations of the form

$$t = \alpha \tilde{t}, \qquad x = \beta y, \qquad u = \gamma v, \qquad \tilde{H} = \frac{\alpha}{\beta\gamma^2} H(\beta y, \gamma v)$$

are admissible for any H.

2. If H does not depend on x, then the Galilean transformation

$$y = x + c\, t, \qquad v = u, \qquad \tilde{H} = H - \frac{1}{2}\, c\, v^2;$$

is admissible.

3. If $H = h(u_x) + c\, xu$, where c is a constant, then the following transformation

$$u \to u + c\, t, \quad H \to H - c\, xu$$

is admissible.

4. If $H = h(u_{xx}) + (c_1 x^2 + c_2 x)u$, where c_1 and c_2 are some constants, then the following transformation

$$u \to u + 2\, c_1 x\, t, + c_2 t, \quad H \to H - (c_1 x^2 + c_2 x)u$$

is admissible.

Remark 2. Sometimes we use the point transformations (2.1) without the condition $\Delta = 1$. Using the properties of the Euler operators that are presented in [6] one can find the form of the transformed equation (1.6):

$$v_t = f\, D_y \left(f\, \frac{\delta \tilde{H}}{\delta v} \right), \tag{2.3}$$

where $f = \Delta^{-1} = f(y, v)$, $\tilde{H} = H\,(D_y \varphi)$. One can easily verify the operator $f \circ D_y \circ f$ is the Hamiltonian one for any f.

2.2. **Canonical densities.** The necessary integrability conditions for equations (1.11) have the form of an infinite chain of the canonical conservation laws

$$\frac{d}{dt}(\rho_n) = \frac{d}{dx}(\theta_n), \quad n = -1, 0, 1, \ldots, \tag{2.4}$$

where the functions ρ_i are defined by a recurrent formula. Following [7], we find that in the case of fifth order equations

$$u_t = F(x, u, u_x, u_2, \dots, u_5) \tag{2.5}$$

the recurrence can be written as follows

$$\begin{aligned}
\rho_{n+4} = {} & \frac{1}{5}\rho_{-1}\theta_n - \frac{1}{5}\rho_{-1}\left(F_0\delta_{n,0} + F_1\rho_n + F_2 D_x(\rho_n) + F_2\sum_{-1}^{n}\rho_i\rho_j + F_3 D_x^2(\rho_n)\right) \\
& - \frac{1}{5}\rho_{-1}F_3\left(\frac{3}{2}D_x\sum_{-1}^{n}\rho_i\rho_j + \sum_{-1}^{n}\rho_i\rho_j\rho_k\right) - \frac{1}{5}\rho_{-1}F_4\left(D_x^3(\rho_n) + 2D_x^2\sum_{-1}^{n}\rho_i\rho_j\right) \\
& - \frac{1}{5}\rho_{-1}F_4\left(-\sum_{-1}^{n}D_x(\rho_i)D_x(\rho_j) + 2D_x\sum_{-1}^{n}\rho_i\rho_j\rho_k + \sum_{-1}^{n}\rho_i\rho_j\rho_k\rho_l\right) \\
& - (\rho_{-1})^{-4}\left(\frac{1}{5}D_x^4(\rho_n) + \frac{1}{2}D_x^3\sum_{-1}^{n}\rho_i\rho_j - \frac{1}{2}D_x\sum_{-1}^{n}D_x(\rho_i)D_x(\rho_j) + \frac{2}{3}D_x^2\sum_{-1}^{n}\rho_i\rho_j\rho_k\right. \\
& \left. - \sum_{-1}^{n}\rho_i D_x(\rho_j)D_x(\rho_k) + \frac{1}{2}D_x\sum_{-1}^{n}\rho_i\rho_j\rho_k\rho_l + \frac{1}{5}\sum_{-1}^{n}\rho_i\rho_j\rho_k\rho_l\rho_m - \rho_{-1}^4\rho_{n+4}\right),
\end{aligned} \tag{2.6}$$

where $n = -4, -3, -2, \dots,\ F_n = \partial F/\partial u_n$ and

$$\rho_{-1} = F_5^{-1/5}.$$

By definition,

$$\sum_{a}^{b}\rho_{I_1}\cdots\rho_{I_k} = \sum_{\substack{I_s\geqslant a,\,1\leqslant s\leqslant k,\\ I_1+\cdots+I_k=b}}\rho_{I_1}\cdots\rho_{I_k}.$$

In particular, we have

$$\sum_{-1}^{-2}\rho_i\rho_j = \rho_{-1}^2, \qquad \sum_{-1}^{-1}\rho_i\rho_j = 2\,\rho_{-1}\rho_0, \qquad \sum_{0}^{-1}\rho_i\rho_j\rho_k = 0,$$

$$\sum_{-1}^{n}\rho_i\rho_j\rho_k = 3\rho_{-1}^2\rho_{n+2} + 6\rho_{-1}\rho_0\rho_{n+1} + \dots, \qquad \sum_{-1}^{n}\rho_i\rho_j\rho_k\rho_l\rho_m = 5\rho_{-1}^4\rho_{n+4} + \dots$$

The first three canonical densities are given by

$$\rho_{-1} = F_5^{-1/5}, \qquad \rho_0 = -\frac{1}{5}F_4\rho_{-1}^5 - 2D_x\ln\rho_{-1},$$

$$\rho_1 = \frac{1}{2}F_4D_x(\rho_{-1}^4) + \frac{2}{5}\rho_{-1}^4D_xF_4 + \frac{2}{25}\rho_{-1}^9F_4^2 - \frac{1}{5}\rho_{-1}^4F_3 - 3(\rho_{-1})^{-3}(D_x\rho_{-1})^2 + 2(\rho_{-1})^{-2}D_x^2(\rho_{-1}).$$

For equations (1.6) we have

$$\rho_{-1} = \left(\frac{\partial^2 H}{\partial u_{xx}^2}\right)^{-1/5}. \tag{2.7}$$

Let us denote $\rho_{-1} = a(x, u, u_x, u_{xx})$. Then

$$\frac{\partial^2 H}{\partial u_{xx}^2} = a^{-5}. \tag{2.8}$$

We use the following notations: $f \sim g$ iff $f - g \in \operatorname{Im} D_x$. In particular, $f \sim 0$ iff $f \in \operatorname{Im} D_x$. We write here D_x instead of $\frac{d}{dx}$ and D_t instead of $\frac{d}{dt}$ for brevity. Thus, all integrability conditions may be written in the following form $D_t\rho_n \sim 0$, $n = -1, 0, \dots$.

We used the following algorithm of checking whether a given function $S(x, u, u_1, \dots, u_n)$ belongs to $\operatorname{Im} D_x$. At first, S has to be linear in the highest derivative u_n. If it holds true, then we can subtract from S a function of the form $D_xQ(x, u, u_1, \dots, u_{n-1})$ such that the difference does nor depend on u_n. Repeating this order lowering procedure, we either arrive at the situation when the function is nonlinear in its highest derivative, or we get zero.

3. Classification

Theorem 2. *If non-linear equation of the form* (1.6) *has infinitely many generalized symmetries*

$$u_{\tau_k} = F_k(x, u, u_x, \dots), \qquad k = 1, 2, \dots$$

and has no symmetries of order p, where $1 < p < 5$, then its Hamiltonian can be reduced to one of the canonical forms (1.7)–(1.10).

Remark 3. If we have $k \neq 0$ in (1.7), then the scaling $u \to u\,k^{1/2},\ x \to x\,k^{-1},\ t \to t\,k^{-4/3}$ brings k to 1. If $k \neq 0$ in (1.10) then we can reduce k to 1 by the scaling $u \to u\,k^{-1},\ x \to x\,k,\ t \to t\,k^{-4}$. Therefore we may assume that $k = 0$ or $k = 1$ for both these Hamiltonians.

Remark 4. All constants in Hamiltonian (1.8) can be normalized by canonical transformations to 1 or 0. If $c_0 \neq 0$ then using the dilatation $u \to \alpha u,\ t \to \alpha^{-1}t,\ \alpha = c_0^{-3/8}$, we obtain $c_0 = 1$. After that we can apply the transformation $u \to u - \frac{1}{2}(c_1x + c_2)$ to obtain the Hamiltonian

$$H = \sqrt[3]{u_{xx}} + \frac{1}{3}\,u^3 + (k_1x^2 + k_2x)u,$$

where k_1 and k_2 are some constants. If $k_1 \neq 0$ the scaling $u \to u\,\mu,\ x \to x\mu^{-4},\ t \to t\mu^{-5}$ with $\mu = k_1^{1/10}$ leads to $k_1 = 1$. Now we reduce k_2 to zero by the translation $x \to x - k_2/2$. If $k_1 = 0$ and $k_2 \neq 0$, we normalize k_2 by 1 with the help of a scaling. Thus, if $c_0 \neq 0$ we have the following three non-equivalent Hamiltonians:

$$H_1 = \sqrt[3]{u_{xx}} + \frac{1}{3}\,u^3 + x^2u, \tag{3.1}$$

$$H_2 = \sqrt[3]{u_{xx}} + \frac{1}{3}\,u^3 + x\,u, \tag{3.2}$$

$$H_3 = \sqrt[3]{u_{xx}} + \frac{1}{3}\,u^3. \tag{3.3}$$

If $c_0 = 0$ and $c_1 \neq 0$ then (1.8) is equivalent to

$$H_4 = \sqrt[3]{u_{xx}} + \frac{1}{2}\,x\,u^2. \tag{3.4}$$

In the case $c_0 = c_1 = 0$ the Hamiltonian is equivalent to

$$H_5 = \sqrt[3]{u_{xx}}. \qquad \square \tag{3.5}$$

Proof of Theorem 2. Consider the first integrability condition $D_t(a) \sim 0$. It can be verified that

$$D_t a \sim -\frac{5}{2}\, u_4^2 a^{-10} D_x \left(a^5 \frac{\partial^2 a}{\partial u_2^2} \right) + O(3), \tag{3.6}$$

where the symbol $O(n)$ denotes terms of differential order not greater then n. Since the right hand side of (3.6) has to belong to $\operatorname{Im} D_x$ it should be linear in the highest derivative. Therefore we get

$$\frac{d}{dx} \left(a^5 \frac{\partial^2 a}{\partial u_2^2} \right) = 0.$$

Integrating this equation we obtain that

$$\frac{\partial^2 a}{\partial u_2^2} = -2\, c_0^2 a^{-5}, \tag{3.7}$$

where c_0 is a constant.

Now we consider the third integrability condition and find that

$$D_t \rho_1 \sim -10 u_5^2 a^{-13} \frac{\partial a}{\partial u_2} \left[2\, u_3 \left(a^2 \frac{\partial a}{\partial u_2} - c_0 \right) \left(a^2 \frac{\partial a}{\partial u_2} + c_0 \right) + a^3 D_x \left(a^2 \frac{\partial a}{\partial u_2} \right) \right] \tag{3.8}$$

$$- \frac{5}{3} u_4^3 a^{-18} \left[2\, u_3 \left(a^2 \frac{\partial a}{\partial u_2} - c_0 \right) \left(a^2 \frac{\partial a}{\partial u_2} + c_0 \right) \left(99\, a^4 \left(\frac{\partial a}{\partial u_2} \right)^2 + 20\, c_0^2 \right) + O(2) \right] + \dots$$

Equating to zero the coefficients at $u_5^2 u_3$ and $u_4^3 u_3$, we obtain

$$\frac{\partial a}{\partial u_2} = z a^{-2},$$

where $z = \pm c_0$. If $z \neq 0$ we reduce z to 1 by the dilatation $u \to \dfrac{u}{3z}$ and arrive at the case

$$\mathbf{A}: \qquad a = (u_{xx} + q(x, u, u_x))^{1/3}.$$

If $z = 0$, then we get

$$\mathbf{B}: \qquad a = a(x, u, u_x).$$

Case A. Integrating equation (2.8) we find that the Hamiltonian is equivalent to

$$H = f(x, u, u_x) - \frac{9}{2}\, a.$$

The first integrability condition yields $\dfrac{\partial^2 f}{\partial u_x^2} = 0$. Since the Hamiltonian is defined up to functions from $\operatorname{Im} D_x$ we set without loss of generality

$$H = h(x, u) - \frac{9}{2}\, a, \qquad a = \sqrt[3]{u_{xx} + q(x, u, u_x)}.$$

It follows from the third integrability condition that

$$q = q_0 + q_1 u_x + q_2 u_x^2 + q_3 u_x^3, \qquad q_i = q_i(x,u).$$

Applying (non-canonical) transformation $y = \varphi(x,u),\ v = \psi(x,u)$, we reduce to zero q_2 and q_3. To do this we can take for φ and ψ any functionally independent solutions of the system of PDEs

$$\begin{aligned}
\varphi_{xx} &= 2\,\frac{\varphi_{ux}\varphi_x}{\varphi_u} - \frac{\varphi_x^2\varphi_{uu}}{\varphi_u^2} + q_0\,\varphi_u - q_1\,\varphi_x + q_2\,\frac{\varphi_x^2}{\varphi_u} - q_3\frac{\varphi_x^3}{\varphi_u^2},\\
\psi_{xx} &= 2\frac{\psi_{xu}\varphi_x}{\varphi_u} - \frac{\varphi_x^2\psi_{uu}}{\varphi_u^2} + \frac{2\,h}{\varphi_u^3}\,(\varphi_{uu}\varphi_x - \varphi_{ux}\varphi_u) + q_0\psi_u - q_1\psi_x\\
&\quad + q_2\,\frac{\varphi_x}{\varphi_u^2}\,(\varphi_u\psi_x - \Delta) + q_3\,\frac{\varphi_x^2}{\varphi_u^3}\,(2\Delta - \varphi_u\psi_x)\,,
\end{aligned}$$

where $\Delta = \varphi_x\psi_u - \varphi_u\psi_x$.

The resulting Hamiltonian has the following structure:

$$\tilde H = \tilde h(x,u) - \frac{9}{2}\,\sqrt[3]{f(x,u)\,u_{xx} + \tilde q_0(x,u) + \tilde q_1(x,u)u_x},$$

where $f = \Delta^{-1}$. The Hamiltonian form of the corresponding equation (2.5) is given by (2.3). The first canonical density for this equation has the form

$$\rho_{-1} = \sqrt[3]{f\,u_{xx} + \tilde q_0 + \tilde q_1 u_x}\,f^{-4/5}.$$

The integrability condition $D_t(\rho_{-1}) \sim 0$ leads to $f = c$, where c is a non-zero constant. We reduce c to 1 by the transformation $t \to t\,c^{-7/3}$. This means that for integrable equations the above transformation $y = \varphi$, $v = \psi$ is a canonical one. Thus we have shown that the Hamiltonian can be reduced to

$$H = h(x,u) - \frac{9}{2}\,a, \qquad a = \sqrt[3]{u_{xx} + q_0 + q_1 u_x},$$

where the Hamiltonian form of the corresponding equation (2.5) is given by (1.6).

It follows from the third integrability condition that

$$q_1 = s_2(x)u^2 + s_1(x)u + s_0(x).$$

Under canonical transformations of the form $y = f(x)$, $v = u/f' + g(x)$ this function changes as follows: $q_1 \to \tilde q_1 = \tilde s_2 u^2 + \tilde s_1 u + \tilde s_0$, where

$$\tilde s_2 = s_2 f', \quad \tilde s_1 = s_1 - 2\,g\,s_2 f', \quad \tilde s_0 = (f')^{-2}(s_0 f' + f'' - g s_1 f'^2 + g^2 s_2 f'^3).$$

If $s_2 \neq 0$, we take $f = 5\int s_2^{-1}dx$ and $g = s_1/10$ to get $\tilde s_2 = 5,\ \tilde s_1 = 0$. If $s_2 = 0$, then $\tilde s_1 = s_1$. Choosing $g = 0$ and taking for f any non-constant solution of the equation $f'' + s_0 f' = 0$,

we arrive at $\tilde{s}_0 = 0$. So we are to consider the cases

$$\textbf{A.1}. \quad q_1 = 5u^2 + s(x), \qquad \textbf{A.2}. \quad q_1 = s(x)\,u.$$

Case A.1. It follows from the third integrability condition that $s(x)$ is a constant. We denote it by $9\,k$. Moreover we find that

$$q_0 = 2\,u\,(u^2 + k)(u^2 + 9\,k).$$

For such q_1 and q_0 the third integrability condition turns out to be equivalent to $h = c_2u^2 + c_1u$ where c_1 and c_2 are some constants. As it was mentioned in Section 2.1, c_1 is a trivial constant and the term c_1u^2 can be removed by the Galilean transformation. So, we obtain the integrable Hamiltonian (1.7).

Case A.2. From the first and third integrability conditions we find that

$$H = \frac{1}{3}p_0(x)\,u^3 + \frac{1}{2}\,p_1(x)u^2 + p_2(x)u - \frac{9}{2}\sqrt[3]{u_{xx} + r_1(x)u + r_0(x)},$$

To simplify this Hamiltonian we use linear (non-canonical) transformations of the form $y = \varphi(x),\ v = u\,g(x) + \psi(x)$. Taking a solution of the PDE system

$$\varphi' = g^2, \quad g'' = 2\,g^{-1}g'^2 + r_1g, \quad \psi'' = 2\,g^{-1}g'\psi' + r_0g$$

for g, φ and ψ, we arrive at the transformed Hamiltonian

$$H = F(x,u) - \frac{9}{2}\Big(u_{xx}f(x)\Big)^{1/3},$$

where $f = g^{-3}$ and $F = h/g^2$ is the third degree polynomial with respect to u.

Since the transformation was not canonical, the Hamiltonian equation now takes the form (2.3). The first canonical density now reads as $\rho_{-1} = {u_{xx}}^{1/3}\,f^{-7/15}$. The first integrability condition immediately leads to the fact that f is a constant. By a dilatation of the form $t \to \lambda t$ we reduce f to 1. This means that for any integrable Hamiltonian we can reduce the coefficients r_1, r_0 to zero by a canonical transformation. Now we find that the polynomial F has the form

$$F = \frac{1}{3}\,c_0\,u^3 + \frac{1}{2}\,(c_1\,x + c_2)u^2 + (c_3\,x^2 + c_4\,x)u,$$

where c_i are some constants. Thus, we obtain Hamiltonian (1.8). All constants c_i are inessential (see Remark 4).

Case B. Integrating equation (2.8), we find that without loss of generality the Hamiltonian can be written in the form

$$H = h(x,u,u_x) + \frac{u_{xx}^2}{2\,a^5}. \tag{3.9}$$

It follows from the first integrability condition that

$$D_x\left(a^3\frac{\partial^2 a}{\partial u_x^2}\right)=0.$$

The solution of this equation is given by

$$a=\sqrt{a_0+a_1u_x+a_2u_x^2}\,,\qquad a_1^2-4\,a_2a_0=c^2,$$

where $a_i=a_i(x,u)$, and c is a constant. It can be verified (see [1]) that a_2 can be reduced to zero by a canonical transformation $y=\varphi(x,u),\ v=\psi(x,u)$. Now the condition $a_1^2-4\,a_2a_0=c^2$ implies that a_1 is a constant. Using a scaling of the form $u\to\lambda u$, we arrive at the following two subcases:

$$\textbf{B.1}.\ a=a(x,u),\qquad\qquad \textbf{B.2}.\ a=\sqrt{u_x+q(x,u)}.$$

Case B.1. It follows from the first integrability condition that

$$\frac{\partial^3 a}{\partial u^3}=0,\qquad \frac{\partial}{\partial x}\left(\frac{\partial^2 a^2}{\partial u^2}-3\left(\frac{\partial a}{\partial u}\right)^2\right)=0,$$

which means that

$$a=s_0+s_1u+s_2u^2,\qquad\qquad \delta=s_1^2-4\,s_2s_0=constant,$$

where $s_i=s_i(x)$. Using linear canonical transformations

$$y=\varphi(x),\qquad v=u(\varphi')^{-1}+f(x)$$

and scalings, we can simplify the function a. As a result we arrive at the subcases

$$\textbf{B.1.1}.\ a=1,\qquad \textbf{B.1.2}.\ a=u,\qquad \textbf{B.1.3}.\ a=u^2+z,$$

where z is a constant.

Case B.1.1. It follows from the third integrability condition that

$$H=\frac{1}{2}u_{xx}^2+\frac{1}{3}f_1u_x^3+\frac{1}{2}f_2u_x^2+f_3,\qquad f_i=f_i(x,u).$$

The fifth integrability condition implies $f_1=c_0,\ f_2=c_1u^2+a_2u+a_3$, where $a_i=a_i(x)$ and c_i are constants such that $c_0(4\,c_0^2-5\,c_1)=0$.

Subcase B.1.1.a. If $c_0\neq 0$, then $c_1=\frac{4}{5}\,c_0^2\neq 0$. Using a canonical transformation of the form $u\to u-f(x)$, we reduce a_2 to zero. It follows from the fifth integrability condition that

$$H=\frac{1}{2}\,{u_{xx}}^2+\frac{1}{3}\,{u_x}^3c_0+\frac{2}{5}\,{u_x}^2{c_0}^2u^2+\frac{8}{1875}\,u^6{c_0}^4.$$

Using a scaling of the form $u\to\lambda u$, we put $c_0=-5/2$ getting Hamiltonian (1.9).

Subcase B.1.1.b. If $c_0 = 0$ and $c_1 \neq 0$, we reduce the function a_2 to zero by the canonical transformation $u \to u - a_2/(2c_1)$. Assuming $a_2 = 0$, we find from the fifth integrability condition that

$$H = \frac{1}{2}u_{xx}^2 + \frac{1}{2}(c_1u^2 + c_2)u_x^2 + \frac{c_1^2}{100}u^6 + \frac{c_1c_2}{20}u^4 + \frac{1}{2}c_3u^2 + c_4u.$$

The constant c_4 is trivial (see Section 2.1) and c_3 can be annihilated by the Galilean transformation. By a transformation of the form $u \to \lambda u$ we reduce c_1 to 10 and get

$$H = \frac{1}{2}\,u_{xx}^2 + 5\,u^2u_x^2 + u^6 + \frac{1}{2}\,c(u_x^2 + u^4).$$

The corresponding evolution equation

$$u_t = D_x\left(u_4 - 10\,u(u\,u_2 + u_x^2) + 6\,u^5 + c\,(2\,u^3 - u_{xx})\right)$$

is a higher symmetry of the mKdV equation $u_t = D_x(u_{xx} - 2\,u^3)$. This equation has Hamiltonian (1.3) with $Q = 1$ and $P = -\frac{1}{2}u^4$.

Subcase B.1.1.c. If $c_0 = c_1 = 0$, integrability conditions imply $a_2 = k = \textit{constant}$ and

$$H = \frac{1}{2}u_{xx}^2 + \frac{1}{2}(k\,u + a_3)u_x^2 + \frac{40\,c_3 + 3\,k^2}{40}u^4 + \frac{1}{3}a_4u^3 + \frac{1}{2}a_5u^2 + a_6u, \qquad a_i = a_i(x),$$

where $k(k^2 + 20\,c_3) = 0$.

I. If $k \neq 0$, then $c_3 = -k^2/20$. Using the shift $u \to u - a_3/k$, we reduce a_3 to zero. After that integrability conditions lead to the fact that a_5 and a_6 are constants and that $a_4 = 0$. The constant a_6 is trivial and a_5 can be reduced to 0 by the Galilean transformation. Using the transformation $u \to -(10/k)\,u$, we obtain

$$H = \frac{1}{2}\,u_2^2 - 5\,uu_x^2 + \frac{5}{2}\,u^4, \qquad u_t = D_x\left(u_4 + 10\,u(u_2 + u^2) + 5\,u_x^2\right).$$

The latter equation belongs to the hierarchy of the KdV equation $u_t = D_x(u_2 + 3\,u^2)$. This equation has Hamiltonian (1.3) with $Q = 1$ and $P = u^3$.

II. If $k = 0$, then the Hamiltonian

$$H = \frac{1}{2}u_{xx}^2 + \frac{1}{2}a_3u_x^2 + c_3u^4 + \frac{1}{3}a_4u^3 + \frac{1}{2}a_5u^2 + a_6u, \qquad a_i = a_i(x)$$

can be simplified by a canonical transformation of the form $u \to u - f(x)$. The coefficients of the Hamiltonian are transformed as follows:

$$\tilde{a}_3 = a_3, \quad \tilde{c}_3 = c_3, \qquad \tilde{a}_4 = a_4 - 12\,c_3f, \qquad \tilde{a}_5 = a_5 + 12\,c_3f^2 - 2\,a_4f,$$

$$\tilde{a}_6 = a_6 - f^{(4)} - 4\,c_3f^3 + a_3f^2 - a_5f + (f'a_6)'.$$

Consider the following alternatives:

a) If $c_3 \neq 0$, then we take $f = a_4/(12\,c_3)$ to get $\tilde{a}_4 = 0$.

b) If $c_3 = 0,\ a_4 \neq 0$, then choosing $f = a_5/(2\,a_4)$ we get $\tilde{a}_5 = 0$.

c) If $c_3 = 0,\ a_4 = 0$, then we consider the normalization $\tilde{a}_6 = 0$.

In the cases a) and b) we obtain non-integrable equations $u_t = D_x(u_4 + 4c_3u^3 + c\,u_2)$ and $u_t = D_x(u_4 + c_4u^2 + c\,u_2)$, $c_4 \neq 0$, correspondingly. For the first of them the ninth integrability condition is not fulfilled and for the second the condition number eleven is broken.

In the case c) a linear equation appears with the Hamiltonian $H = \frac{1}{2}(u_{xx}^2 + a(x)u_x^2 + b(x)u^2)$.

Case B.1.2. Here we consider the Hamiltonians of the form

$$H = h(x, u, u_x) + \frac{u_{xx}^2}{2\,u^5}.$$

It follows from the third integrability condition that

$$D_x\left(u^7\frac{\partial^4 h}{\partial u_x^4}\right) = 0 \text{ or } \quad h = c_1\frac{u_x^4}{u^7} + q_1u_x^3 + q_2u_x^2 + q_3u_x + q_4, \qquad q_i = q_i(x, u).$$

The dependence of the functions q_i on u can be specified by the third and fifth integrability conditions:

$$H = \frac{u_{xx}^2}{2\,u^5} - \frac{15}{8}\frac{u_x^4}{u^7} + \frac{1}{2}u_x^2\left(\frac{s_1}{u^5} + \frac{s_2}{u}\right) + \frac{s_2^2}{50}u^5 - \frac{1}{2}s_3u^2 - \frac{u^{-3}}{150}(10\,s_1'' - 3\,s_1^2) - \frac{u}{15}(5\,s_2'' + s_1s_2), \tag{3.10}$$

where $s_i = s_i(x)$. The functions s_1, s_2 and s_3 are changed under the canonical transformation $y = \varphi(x)$, $v = u/\varphi'$ as follows:

$$\tilde{s}_1 = \frac{1}{2}(\varphi')^{-4}(10\,\varphi'''\varphi' - 15\,\varphi''^2 + 2\,s_1\varphi'^2), \qquad \tilde{s}_2 = s_2\varphi'^2, \qquad \tilde{s}_3 = s_3\varphi'.$$

Choosing φ as a nonzero solution of the equation $10\,\varphi'''\varphi' - 15\,\varphi''^2 + 2\,s_1\varphi'^2 = 0$, we obtain $\tilde{s}_1 = 0$. In this case the integrability conditions 1-7 are equaivalent to equations

$$s_2^{(5)} = 0, \qquad s_3''' = 0, \qquad s_3s_2' = 2s_2s_3'.$$

Two solutions: (i) $s_3 \neq 0$, $s_3 = c_0 + c_1x + c_2x^2$, $s_2 = k\,s_3^2$, and (ii) $s_3 = 0$ and $s_2(x)$ is a polinomial of degree not greater than 4, lead to

$$H_1 = \frac{u_{xx}^2}{2\,u^5} - \frac{15}{8}\frac{u_x^4}{u^7} + s_3^2\frac{k\,u_1^2}{2\,u} + \frac{k^2}{50}s_3^4u^5 - \frac{1}{2}s_3u^2 - \frac{2}{3}k\,u(s_3s_3'' + s_3'^2),$$

and

$$H_2 = \frac{u_{xx}^2}{2\,u^5} - \frac{15}{8}\frac{u_x^4}{u^7} + \frac{s_2}{2}\frac{u_x^2}{u} + \frac{s_2^2}{50}u^5 - \frac{u}{3}s_2''.$$

Equations (1.6) corresponding to both H_1 and H_2 have third order symmetries of the form

$$u_\tau = D_x\left(\frac{u_{xx}}{u^3} - \frac{3}{2}\frac{u_x^2}{u^4} + u^2P(x)\right),$$

where $P = -\frac{3}{5}ks_3^2$ and $P = -\frac{3}{5}s_2$ correspondingly. These symmetries are generated by Hamiltonians of the form (1.4).

Case B.1.3. For Hamiltonians of the form

$$H = h(x, u, u_x) + \frac{u_{xx}^2}{2\,\mu^5}, \qquad \mu = u^2 + z \tag{3.11}$$

the first integrability condition leads to

$$\frac{\partial h}{\partial x} = D_x f(x,u)$$

for some function f. Therefore h has the form $h = D_x g + h_0(u,u_x)$ and without loss of generality we assume that $h = h(u,u_x)$.

It follows from the third integrability condition that

$$D_x\left(\mu^7\frac{\partial^4 h}{\partial u_x^4} + 160\,\mu\right) = 0,$$

and therefore the Hamiltonian is equivalent to

$$H = \frac{u_{xx}^2}{2\,\mu^5} - \frac{20}{3}\frac{u_x^4}{\mu^7}\big(c_1+\mu\big) + \frac{1}{3}q_1u_x^3 + \frac{1}{2}q_2u_x^2 + q_3, \tag{3.12}$$

where $q_i = q_i(u)$ and c_1 is a constant. From the third and fifth integrability conditions we derive two relations $(8\,c_1 + 9\,z)(4\,c_1 + 5\,z) = 0$ and $(8\,c_1 + 9\,z)(6\,c_1 + 7\,z) = 0$, which implies $c_1 = -9\,z/8$. Taking this into account, we find that the third integrability condition is equivalent to the following relations:

$$\mu^3q_2''' + 24\,u\,\mu^2q_2'' + 12\,\mu(14\,\mu - 11\,z)q_2' + 24\,u(14\,\mu - 5\,z)q_2 = 0, \tag{3.13}$$

$$z\,(5\,q_3''' - 2\,\mu^5q_2q_2' - 18\,u\,\mu^4q_2^2) = 0, \qquad z\,q_1 = 0. \tag{3.14}$$

From the fifth integrability condition we additionally find

$$u\,q_1' = -10\,q_1, \qquad q_1(5\,u^2q_2'' + 70\,uq_2' + 210\,q_2 - 8\,u^{12}q_1^2) = 0. \tag{3.15}$$

Consider the following two subcases corresponding to $z = 0$ and $z \neq 0$ in (3.12)–(3.14).

Subcase B.1.3.a. If $z = 0$, we find from (3.13) and (3.15) that

$$q_1 = k_1u^{-10}, \qquad q_2 = k_2u^{-8} + k_3u^{-7} + k_4u^{-6},$$

where k_i are constants. The fifth integrability condition leads to

$$q_3 = \frac{1}{2}k_5u^{-2} - k_6u^{-1} + \frac{4\,k_1^2 - 15k_2}{1500\,u^4}(k_2 + 3\,k_3u),$$

where

$$k_1(5\,k_2 - 4\,k_1^2) = 0, \quad (5\,k_2 - 4\,k_1^2)(10\,k_6 + 3\,k_3k_4) = 0, \quad (5\,k_2 - 4\,k_1^2)(5\,k_3^2 + 2\,k_0k_4 - 100\,k_5) = 0.$$

Additional algebraic relations for k_i follows from the seventh integrability condition. The system of algebraic equations thus obtained has four solutions. One solution corresponds to

the integrable Hamiltonian (1.10). The remaining solutions generate the following Hamiltonians:

$$H_1 = \frac{1}{2}\frac{{u_{xx}}^2}{u^{10}} - \frac{20}{3}\frac{{u_x}^4}{u^{12}} + \frac{{u_x}^2}{u^8}(c_1\,u^2 + 2\,c_2\,u + c_3) + \frac{c_3}{25}\frac{5\,c_1\,u^2 + 6\,c_2\,u + c_3}{u^4} + \frac{2}{5}\,c_2\,\frac{2\,c_1\,u + c_2}{u^2},$$

$$H_2 = \frac{1}{2}\frac{{u_{xx}}^2}{u^{10}} - \frac{20}{3}\frac{{u_x}^4}{u^{12}} + \frac{1}{2}\frac{{u_x}^2}{u^7}(10\,c_1 + c_2\,u) + \frac{5}{2}\frac{{c_1}^2}{u^2} + \frac{c_2\,c_1}{u},$$

$$H_3 = \frac{1}{2}\frac{{u_{xx}}^2}{u^{10}} - \frac{20}{3}\frac{{u_x}^4}{u^{12}} + \frac{c_1}{2}\frac{u_x^2}{u^6} - \frac{c_2}{u}.$$

The Hamiltonians H_1 and H_2 correspond to fifth order symmetries for equations

$$u_t = D_x\left(\frac{u_{xx}}{u^6} - 3\frac{u_x^2}{u^7} + \frac{1}{5}(2\,c_2 u^{-2} + c_3 u^{-3})\right)$$

and

$$u_t = D_x\left(\frac{u_{xx}}{u^6} - 3\frac{u_x^2}{u^7} + \frac{c_1}{u^2}\right),$$

correspondingly. The first of these equations has Hamiltonian (1.3) with $Q = u^2$ and $\forall P$. The second equation has Hamiltonian (1.3) with $Q = u^2$ and $P = -c_1 u$.

If $c_2 \neq 0$, the equation corresponding to H_3 does not satisfy the eleventh integrability condition. In the case $c_2 = 0$ we get a symmetry of equation

$$u_t = D_x\left(\frac{u_{xx}}{u^6} - 3\frac{u_x^2}{u^7}\right).$$

This equation has Hamiltonian (1.3) with $Q = u^2$ and $P = 0$. The reciprocal transformation $dy = \rho_{-1}dx + \theta_{-1}dt,\ v(t,y) = 1/u(t,x)$ linearizes the equation. The Hamiltonian equation for H_3 with $c_2 = 0$ is also linearizable.

Subcase B.1.3.b. If $z \neq 0$ in Hamiltonian (3.11), then we find from equation (3.12), (3.13) and (3.14) that

$$H = \frac{u_{xx}^2}{2\,\mu^5} - \frac{5}{6}\frac{u_x^4}{\mu^7}(8\,\mu - 9\,z) + 5\,\varphi\,u_x^2 + \psi, \tag{3.16}$$

where $\varphi = q_2/10, \quad \psi = q_3,$

$$\mu = u^2 + z, \qquad \varphi = -\frac{z\,(2\,k_1 u + k_2)}{\mu^5} + \frac{k_1 u + k_2}{\mu^4} + \frac{k_3}{\mu^3},$$

$$\psi = \frac{z}{2}\,\frac{4\,{k_1}^2 z - 4\,k_1\,k_2\,u - {k_2}^2}{\mu^3} + \frac{3\,k_1\,k_2\,u - 4\,{k_1}^2 z + {k_2}^2}{\mu^2} + \frac{5}{2}\,\frac{4\,k_1\,k_3\,u + 2\,k_2\,k_3 + {k_1}^2}{\mu}.$$

Here k_i are constants. The corresponding Hamiltonian equation is a symmetry of the following third order equation

$$u_t = D_x\left(\frac{u_{xx}}{\mu^3} - 3\frac{u\,u_x^2}{\mu^4} + \frac{k_2 u - 2\,z\,k_1}{\mu^2} + \frac{k_1}{\mu}\right).$$

This equation has Hamiltonian (1.3) with $Q = \mu = u^2 + z,\ z \neq 0$ and $\forall P$.

Case B.2. In this case $a=\sqrt{u_x+q(x,u)}$ and the Hamiltonian has the form

$$H=h(x,u,u_x)+\frac{1}{2}\frac{u_{xx}^2}{a^5}.$$

The first integrability condition implies the following equation

$$\frac{\partial}{\partial u_x}\left(a^3\frac{\partial^2 h}{\partial u_x^2}\right)=\frac{105}{8}f_1\,a^{-8}-\frac{5}{2}\,f_2a^{-6}+\frac{5}{8}\,f_3a^{-4},$$

where

$$f_1=(q_x-qq_u)^2,\quad f_2=2\,q^2q_{uu}-4\,qq_{ux}-5\,q_uq_x+5\,qq_u^2+2\,q_{xx},\quad f_3=8\,qq_{uu}-q_u^2-8\,q_{ux}. \tag{3.17}$$

Integrating the equation for h, we found that the Hamiltonian is equivalent to

$$H=h_1(x,u)+a\,h_2(x,u)-\frac{1}{2}f_1a^{-5}+\frac{1}{3}f_2a^{-3}-\frac{5}{6}f_3a^{-1}+\frac{1}{2}\frac{u_{xx}^2}{a^5}, \tag{3.18}$$

where f_i are defined by (3.17), h_1 and h_2 are some functions. It follows from the first integrability condition that

$$q^{(5)}(u)=0,\qquad h_1'''(u)=0,\qquad D_x\left(h_2-\frac{10}{3}q_{uu}\right)=0, \tag{3.19}$$

$$q_xh_{1,uu}+2qh_{1,uux}-q_uh_{1,ux}-h_{1,uxx}=0. \tag{3.20}$$

Integrating (3.19), we get

$$q=q_1u^4+q_2u^3+q_3u^2+q_4u+q_5,\quad h_1=\frac{1}{2}s_1u^2+s_2u,\quad h_2=\frac{10}{3}(q_{uu}+c_0),$$

where $q_i=q_i(x)$, $s_i=s_i(x)$ and c_0 is a constant.

The functions h_1 and q_i transform under canonical transformation $y=\varphi(x),\ u=v/\varphi'+\psi(x)$ as follows:

$$\tilde h_1=\frac{1}{2}s_1\varphi' v^2+(s_2-s_1\varphi'\psi)v \tag{3.21}$$

and

$$\begin{aligned}
&\tilde q_1=q_1\varphi'^2,\quad \tilde q_2=\varphi'(q_2-4\,q_1\varphi'\psi),\quad \tilde q_3=q_3-3\,q_2\varphi'\psi+6\,q_1(\varphi'\psi)^2,\\
&\tilde q_4=\varphi'^{-1}(q_4-2\,q_3\varphi'\psi+3\,q_2(\varphi'\psi)^2-4\,q_1(\varphi'\psi)^3-\varphi'^{-1}\varphi''),\\
&\tilde q_5=\varphi'^{-2}\big(q_5-q_4\varphi'\psi+q_3(\varphi'\psi)^2-q_2(\varphi'\psi)^3+q_1(\varphi'\psi)^4-(\varphi'\psi)'\big).
\end{aligned} \tag{3.22}$$

Let us consider the following two alternatives

$$\textbf{B.2.a}.\quad h_1\neq 0;\qquad\qquad \textbf{B.2.b}.\quad h_1=0.$$

Subcase B.2.a.1. Suppose $s_1\neq 0$; taking $\varphi'=1/s_1$ and $\psi=s_2$, we obtain $\tilde h_1=\frac{1}{2}v^2$. In this case it follows from equation (3.20) that $q_x=0$. Since the Hamiltonian does not depend

on x we may remove the term $\frac{1}{2}v^2$ from $\tilde{H}$ by the Galilean transformation to reduced H to the following form

$$H = \frac{1}{2}\frac{u_{xx}^2}{a^5} + \frac{10}{3}a\,(q'' + c_0) - \frac{(qq')^2}{2\,a^5} + \frac{2q^2q'' + 5\,qq'^2}{3\,a^3} + \frac{5}{6}\,a^{-1}(q'^2 - 8\,qq''), \tag{3.23}$$

where $a = \sqrt{u_x + q(u)}$ and $q^{(5)} = 0$. Equation (1.6) generated by this Hamiltonian is a fifth order symmetry for the equation (see [1])

$$u_t = D_x\left(\frac{u_{xx}}{a^3} + q'\left(\frac{3}{a} - \frac{q}{a^3}\right)\right).$$

This equation has Hamiltonian (1.5) with $P = q$.

Subcase B.2.a.2. If $s_1 = 0$ then $\tilde{h}_1 = h_1 = s_2 u$. In the case $s_2' = 0$ the term $h_1 = c\,u$ is trivial and we have the contradiction $h_1 = 0$, hence $s_2' \neq 0$. Then equation (3.20) takes the form $q_u = -s_2''/s_2'$, therefore $q_1 = q_2 = q_3 = 0$ and $s_2'' + q_4 s_2' = 0$. It follows from formulas (3.22) that we can choose φ and ψ such that $\tilde{q}_4 = \tilde{q}_5 = 0$. Now we have $q = 0$ and therefore $s_2'' = 0$. The Hamiltonian takes the form

$$H = c\,x\,u + \frac{10}{3}c_0 u_x^{1/2} + \frac{1}{2}\frac{u_{xx}^2}{u_x^{5/2}},$$

where c is a constant. The transformation $u \to u + ct$ brings c to zero and the Hamiltonian turns out to be a particular case of (3.23).

Subcase B.2.b. If $h_1 = 0$ then

$$H = \frac{10}{3}(q_{uu} + c_0)\,a - \frac{1}{2}f_1 a^{-5} + \frac{1}{3}f_2 a^{-3} - \frac{5}{6}f_3 a^{-1} + \frac{1}{2}\frac{u_{xx}^2}{a^5}, \tag{3.24}$$

where f_i are given by (3.17). It easy to see from (3.22) that we can reduce the Hamiltonian to one of the following :

B.2.b.1. $q_1 = 1,\ q_2 = 0$; **B.2.b.2**. $q_1 = 0,\ q_2 = 1,\ q_3 = 0$; **B.2.b.3**. $q_1 = q_2 = q_4 = q_5 = 0$.

The first integrability condition results in the equation $q_x = 0$ for all of these cases. Therefore we have Hamiltonians that can be obtained from formula (3.23) as partial cases. The theorem is proved. □

Remark 5. The equation with Hamiltonian (1.9) is well known. It is just equation (3.6) in the list from the survey [7] . The Hamiltonian equation corresponding to (1.10) can be reduced to an equation of the form

$$u_t = u_5 + F(x, u, u_x, u_2, u_3, u_4) \tag{3.25}$$

by the standard reciprocal transformation (see [3], section 1.4)

$$dy = \rho_{-1}dx + \theta_{-1}dt, \qquad v(t, y) = u(t, x), \tag{3.26}$$

where ρ_{-1} is the first canonical density and θ_{-1} is the correspondent flux. The resulting equation coincides with equation (3.12) from [7] up to the differential substitution $v = 2\,w_y^{-1/2}$. Notice that the transformation $v = (w - k/2)^{-1}$ leads to a simpler then (3.12) equation

$$w_t = D_y\Big(w_4 + 10\,w_y\,w_{yy} - 20\,w_{yy}\,w^2 - 20\,{w_y}^2 w + (k - 2\,w)^2(4\,w^3 + 4\,k\,w^2 + 3\,k^2 w + 2\,k^3)\Big).$$

To prove the integrability of equations with Hamiltonians (1.7) and (1.8) one could find differential substitutions that reduce them to known equations of the form (3.25). We have verified that these two equations have local conservation laws of orders 3 and 5. Also we have found generalized symmetries of order 7 for these equations. In the both cases these symmetries have the form

$$u_\tau = D_x\frac{\delta\rho_1}{\delta u},$$

where ρ_1 is the canonical density for the corresponding fifth order equation. In particular, for equation with Hamiltonian (1.8) we have $\rho_1 \sim u_{xxx}^2 u_{xx}^{-7/3}$ and the seventh order symmetry is given by

$$u_\tau = D_x\frac{\delta}{\delta u}\left(\frac{u_{xxx}^2}{{u_{xx}}^{7/3}}\right). \qquad \square$$
